COLLECTED AND DESCRIBED BY

M. ALCIDE D'ORBIGNY,

In the "Voyage dans l'Amérique Méridionale."

LONDON:

PRINTED BY ORDER OF THE TRUSTEES.

1854.

PRINTED BY TAYLOR AND FRANCIS,
RED LION COURT, FLEET STREET.

P R E F A C E.

THE specimens of SHELLS in the following List marked B.M. were received from Professor Alcide d'Orbigny, as the type specimens, collected, described and figured by him in the Mollusca Part of the "Voyage dans l'Amérique Méridionale, le Brésil, la république orientale de l'Uruguay, la république Argentine, la Patagonie, la république du Chili, la république de Bolivia, la république de Pérou, exécuté pendant les années 1826 à 1833, par Alcide d'Orbigny. Ouvrage dédié au Roi, et publié sous les auspices de M. le Ministre de l'Instruction publique." Paris, 4to. 1847.

The specimens are fastened on their original Pasteboard Trays, named by M. d'Orbigny, and marked with their special habitats; and generally there is a series of different ages of each species, especially of those from the South American rivers and ponds.

Asolene Platæ, d'Orb.
Buenos Ayres.

The *Ampullariadæ* with horny opercula, as *Ceratodes* and *Pomus* and *Lanistes*, have an elongated siphon, while those which have a shelly operculum, as *Ampullaria* and *Ampulloidea*, are without any appearance of that organ; this is also the case in the Indian species. See Mrs. Gray's "Figures of Mollusca," for the animals of this family.

Order V. PECTINIBRANCHIA.

Fam. 3. LITTORINIDÆ.

333. VOLUTA ANCILLA, *Solander*, *d'Orb. Voy.* v. 425. B.M.
Voluta Magellanica et V. spectabilis, *Gmelin.*
Voluta gracilis, *Wood.*
Patagonia; Magellan Straits.

334. **VOLUTA FESTIVA**, *Lamk.*, *d'Orb. Voy.* v. 426. B.M.
 Patagonia to Magellan Straits.
 This is *Voluta Beckii*, Brod.

335. **VOLUTA TUBERCULATA**, *Gray*, *d'Orb. Voy.* v. 426. B.M.
 Patagonia to Magellan Straits.

Voluta Magellonica, *V. festiva* and *V. tuberculata* appear to be varieties of the same species, differing in the nodulousness of the whorls and the length of the spire. They differ from *V. ancilla* in being shorter and more ventricose and of a thicker consistence. The younger specimens of *V. ancilla* are generally rather thin, but sometimes the older ones are very heavy and solid. *V. Beckii*, Broderip, is only a large specimen of *V. festiva* of d'Orbigny: there is a specimen of the same size in the collection from Patagonia. This species is nearly as large as *V. magnifica*, and like it an inhabitant of the colder regions.

Murex Magellanicus, *M. Patagonicus* and *M. varians* are varieties of a most variable species. The lamellæ are sometimes very close, regular, crowded (*M. Magellanica*) ; at others few and far apart, giving an angular shape to the body whorl (*M. Patagonica*) ; often completely wanting, the shell being only slightly spirally striated (*M. varians*). They clearly pass into each other, and vary greatly in the thickness of the shell : those that are closely lamellar are generally thin and brittle ; the older ones, without lamellæ, are thick and solid, as in our *Purpura lapillus*, showing that the absence of the lamellæ and thickness of the shell depend on the locality.

These shells also vary in the size of the cavity on the front of the axis.

Calyptræa quiriquina, C. rugosa, C. lignaria and *C. imbricata* are varieties of the same species, differing in the smoothness or *costation* of the outer surface; some specimens which are costate when young become smooth as they increase in size and *vice*

versá, and differ in shape according to the form of the body to which they happen to be attached. It is doubtful if *C. auriculata* is distinct from them; it is probably only a variety living in more sheltered places, where the mantle is furnished with elongated bands forming tubular sheaths on the outer surface of the shell. In all the species the *cup* in the younger specimens is attached by a considerable portion of its outer surface to the disc of the shell; in the older ones, the lower part of it is only attached to the shell by a single point.

C. Patagonica, *C. arcuata* and *C. protea* are only varieties of *C. dilatata*, caused by the form of the substance to which they are attached. They are often parasitic on each other. It may be doubtful if the Patagonian specimens of *C. aculeata* are not also varieties of this species, and distinct from those found in Rio de Janeiro, *C. foliacea* being apparently intermediate between *C. dilatata* and the specimen of *C. aculeata* from Peru. Indeed the species of these Mollusca require other characters to distinguish them, besides the general form of the shell and the structure of its surface: each species presents the same variety, according to the locality and form of the surface to which it has been attached; and these forms from different localities have been considered the same species, instead of varieties of some peculiar local species; hence *C. fornicata*, *C. aculeata* and *C. unguis* have been said to be found in many parts of the world, which is inconsistent with our knowledge as regards other Mollusca, but may be the case with these, as they sometimes attach themselves to ships, floating wood, &c., and may be thus carried from one part of the world to the other, and hence obtain a larger geographic distribution than other Mollusca.

The outline of the front edge of the inner lip appears to be changed, as well as the outer form of the shell, by the form of the substance to which the animal is attached; thus in the *unguiform* varieties of *C. dilatata* the front edge of the inner lip is straight, while in most other varieties it is produced, rounded, with a deep sinus on the left side.
